Global Conflict Monitor

Project Description, Screenshots, AI Use, and Reflection

Project description

Global Conflict Monitor is a React dashboard for students and general readers who want a quick overview of international conflict news and a clearly labeled demonstration risk indicator. It includes a home screen with a fixed 15% estimate, a news feed, and an analysis screen with a sample line chart and risk factors. The news feed retrieves articles from the GDELT DOC 2.0 API and filters for English-language sources. React Router handles navigation; Bootstrap and React-Bootstrap provide layout styling, React Icons supplies icons, and Chart.js renders the chart. The displayed probability is illustrative, not a forecast.

GitHub Pages application: Not deployed yet - add the live URL before submission.

AI usage statement

AI assistance was used to scaffold and troubleshoot the React project, identify missing dependencies and incorrect imports, and diagnose the news feed's CORS problem. I used suggestions to add a Vite development proxy, filter the GDELT query to English-language sources, and simplify custom CSS class names. I reviewed the changes and checked the app's three routes in the browser and the production build. The displayed risk percentage and chart values are sample data; AI did not verify them as a scientific model. I remain responsible for reviewing and explaining the final code.

Reflection

The most challenging part was getting external news data to load reliably in the browser. The initial fetch failed with a CORS error, and the React stack trace pointed into useEffect, which made it look like a hook problem. Checking the browser console and installed dependencies showed React was installed only once; the actual failure was the cross-origin request. I routed the request through Vite's development proxy and added GDELT's source-language operator to limit results to English-language articles. During testing, the API also returned HTTP 429, so rate limiting can temporarily prevent articles from appearing. A production deployment would need its own serverless or API proxy because Vite's proxy only runs in development.

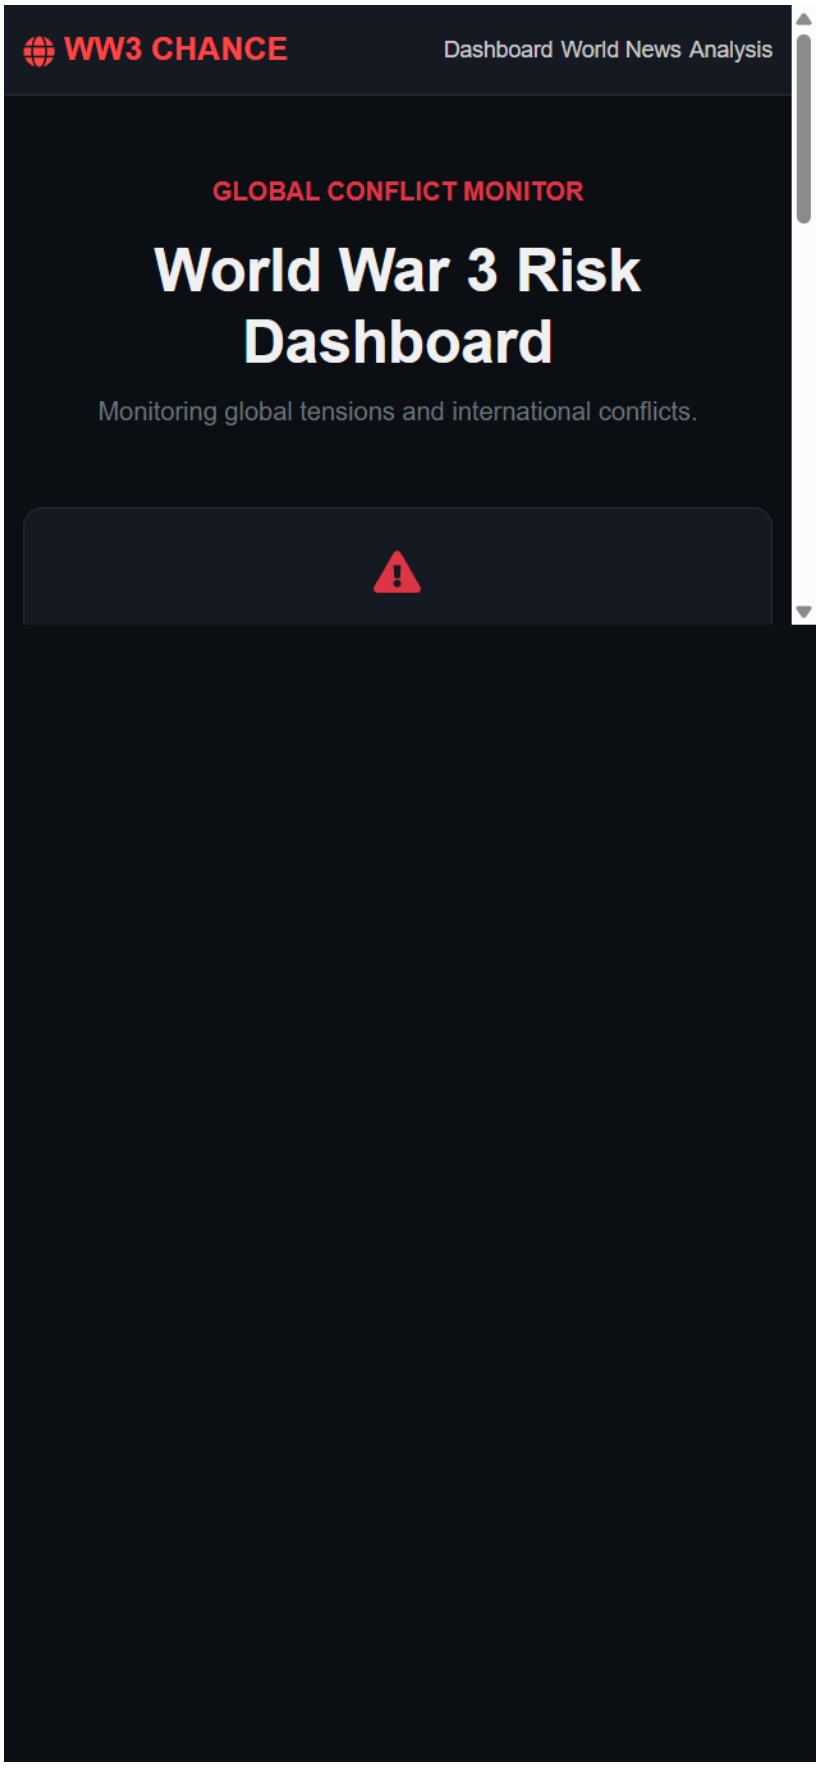

Starting the app also uncovered missing dependencies and imports that pointed to page filenames that did not exist. Installing the packages referenced in the source and correcting those imports made the routes build and render. That reinforced the importance of checking the running app as well as its production build: a successful compile alone did not reveal the CORS problem.

For the design, I kept the application to three screens rather than adding a heavier dashboard framework. React Router gives each screen a clear route, Bootstrap handles responsive layout, and React Icons keeps the navigation and page symbols consistent. Chart.js was a practical choice for the line graph because it supports responsive charts without requiring a separate charting service. I also labeled the risk percentage and chart values as demos; presenting a static number as a real prediction would be misleading.

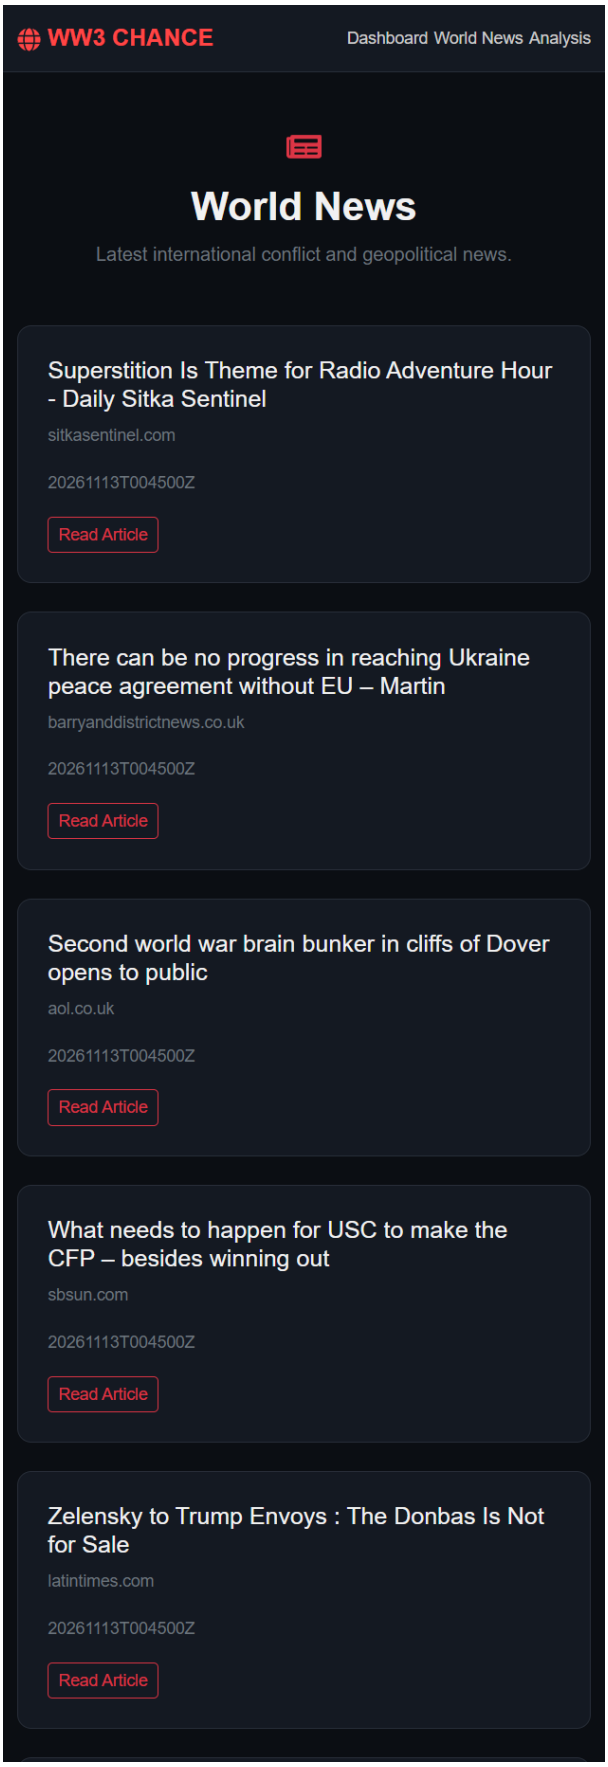

If I had more time, I would replace the sample values with transparent indicators from reputable sources and show each source, timestamp, calculation, and uncertainty. I would improve the news page with clear retry and rate-limit states and add tests for route rendering and API failure handling. I would also check keyboard accessibility and mobile

layouts, then add a production API proxy and deploy the app to GitHub Pages. The goal would be to make the app more reliable and accessible while communicating uncertainty instead of implying that geopolitical risk can be summarized by one definitive percentage.
